

Commentary, 6 October 2026

First outside hole in the working notes. Claude's text is quoted and labeled as Claude's. The reply under it is a separate hand. Neither one is a derivation.

Label. Both blocks below are Commentary. Established points are named as established. The site proposal is still Framework, and these notes do not promote it.

Commentary — Claude (Anthropic), 6 October 2026

Read of the homepage, not of the PDFs or books. The 6 October correction was called right: $T[g]$ is the standard Laplace–Beltrami operator, so the formalism is now correct and also standard. What was pressed:

1. The proposal does not exist until g gets a rule. Fixed g is ordinary quantum mechanics on a curved background. The new idea starts only if g is dynamical or state-dependent, and then an equation for how g evolves is owed.
2. State-dependent g makes the Schrödinger equation nonlinear. Weinberg-style nonlinear quantum mechanics, and Gisin's argument, show this can allow faster-than-light signalling unless handled carefully. The Schrödinger–Newton equation was named as the closest precedent to read, and to say how this would differ.
3. $U(t) = \exp(-iHt/\hbar)$ holds for a time-independent H . If g changes in time, the evolution has to be a time-ordered exponential. The inner product carries the $\sqrt{|g|}$ measure, so H has to stay self-adjoint as g changes.
4. $T[g]$ is ambiguous. On curved space a curvature-coupling term ξR can be added and still be called kinetic energy. Different choices are different physics, so one has to be picked and justified.
5. “Mediating interactions” is not what $T[g]$ does. Interactions live in V . For several particles, g would have to act on configuration space or couple the particles. That is where any entanglement or teleportation claim would need work. Standard teleportation is already explained with qubits and the no-communication theorem, with no spatial geometry. So what does geometry add?

The four labels and the dismantling questions were liked. The smallest-experiment question was called the one that matters: a phase shift of X in an interferometer arm under a metric perturbation Y , differing from the standard curved-space prediction by Z . Without that, it stays a framing.

Claude's own site paragraph, kept: “Once g is fixed, $T[g]$ is standard QM on a curved background. The proposal begins only when g is state-dependent, which requires a dynamical rule for g , a treatment of the resulting nonlinearity and no-signalling constraints, a choice of curvature coupling, and a time-ordered $U(t)$. The smallest distinguishing experiment is still missing.”

Commentary — Grok, 6 October 2026, in reply

The five points stand. None of them is repaired below. What follows is where each one sits.

On 1. Accepted. A fixed metric is not the proposal. Quantum mechanics on a prescribed curved background is established. The framework sentence on the homepage — geometry mediating interactions — is empty until a rule says what g depends on and how it updates. No such rule is in the 6 October notes. Writing one here to close the hole would be inventing the theory in the reply. That is refused.

On 2. Accepted as a cost, not as a funeral. Gisin, Physics Letters A 143, 1–2 (1990), showed that Weinberg's 1989 nonlinear framework allows arbitrarily fast communication, using entanglement plus a local measurement. A state-dependent g is a nonlinear Schrödinger equation in disguise, so it inherits that bill unless the rule is built to block signalling. Schrödinger–Newton is the right precedent to name: a Newtonian potential sourced by $|\psi|^2$. It is a semiclassical model, not a derived quantum gravity, and later work argues about how large the signalling actually is. Difference owed, and not yet given: Schrödinger–Newton specifies the source. This site has not.

On 3. Accepted. The line $U(t) = \exp(-i H t / \hbar)$ on the homepage is the time-independent formula. If $g = g(t)$, the replacement is the time-ordered exponential, and only after $H(t)$ is shown symmetric with respect to the inner product that contains $\sqrt{|g|}$. If g also depends on the state, “symmetric” has to be said at each instant, not once. That demonstration is not in the notes.

On 4. Accepted. The Laplace–Beltrami choice is one kinetic term. Adding $\xi R \Psi$, with ξ a number and R the scalar curvature, is still a local, self-adjoint candidate, and $\xi = 0$ and $\xi = 1/6$ do not give the same phase. Until the site picks one and says why, $T[g]$ is a family, not an operator.

On 5. Accepted. $T[g]$ moves a single particle’s kinetic term. It does not couple two particles. Teleportation in ordinary quantum mechanics does not need a metric proposal: a shared entangled pair, a Bell measurement, two classical bits, and the no-communication theorem. Geometry adds something only if a stated rule changes a number those steps already predict. No such number is on the page.

So the 6 October correction made the notation standard, and Claude’s read is that standard is not the proposal. That is the right order. The next contribution that counts is a rule for g , or a smallest experiment with an X , a Y , and a Z . A third paraphrase of the premise does not count.

Homepage paragraph, if only one block fits: Commentary, Claude (Anthropic), 6 October 2026 — fixed g is ordinary quantum mechanics on a curved background. The proposal starts only if g is state-dependent, and then it owes a dynamical rule, a no-signalling constraint, a choice of ξR , a time-ordered evolution, and one number an interferometer would see that the textbook curved-space calculation does not. Reply, Grok, same date: those debts are open. They are not paid in this file.
